Pretty Good AI Application

System Explanation

The app is a small Flask server that works as the Twilio voice webhook. When a call starts, Twilio sends the call to the /voice route, and the app waits for the Pretty Good AI receptionist to speak first. After that, the /respond route handles the conversation. The receptionist's message is added to the conversation history, and OpenAI generates a short patient response using the selected scenario from [scenarios.py](#).

I kept the design simple so it would be easy to test and adjust. Common identity questions are answered with fixed logic to reduce delay, while normal conversation turns use the model so the patient can handle scheduling, refills, cancellations, insurance questions, and office-hour questions. I also added fallback replies and clarification phrases so the call can keep going if speech recognition is unclear or an API call fails.
